## 3 Embedding

- $\mathcal{E}$ -completion
- Simple completions

Propositional languages  $\mathcal{L}$  and  $\mathcal{L}^-$ :

- an infinite set of propositional variables  $p, q, \dots$ ;
- connectives:  $\wedge, \vee, \rightarrow, \neg$  (assertoric connectives) and  $\Box$  (a unary modality);

$\mathcal{L}$  is the full language above,  $\mathcal{L}^-$  is the assertoric part of  $\mathcal{L}$ .  
Formulas in  $\mathcal{L}^-$  are denoted by letters  $A, B, \dots$

**KM** is **Int** understood in language  $\mathcal{L}$  plus the following formulas as axioms:

- $p \rightarrow \Box p$
- $(\Box p \rightarrow p) \rightarrow p$
- $\Box p \rightarrow (q \vee (q \rightarrow p))$

closed under substitution and detachment (*modus ponens*).

# Kuznetsov's Theorem

## Theorem (Kuznetsov's Theorem)

For any formulas  $A$  and  $B$  of  $\mathcal{L}^-$ ,

$$\mathbf{Int} + A \vdash B \Leftrightarrow \mathbf{KM} + A \vdash B.$$

- Why is **KM** interesting?
- Why is Kuznetsov's Theorem interesting?

**KM** nowadays is mentioned in connection with **Lax** (Fairtlough-Mendler) or **mHC** (Esakia). However, having been defined in the end of the 1970s, it stemmed from a different source.

# Kuznetsov's Theorem

The following diagram is commutative:

$$\begin{array}{ccc} \text{Ext}\mathbf{GL} & \xrightarrow{\kappa} & \text{Ext}\mathbf{KM} \\ \downarrow \mu & & \downarrow \lambda \\ \text{Ext}\mathbf{Grz} & \xrightarrow{\sigma} & \text{Ext}\mathbf{Int} \end{array}$$

Here  $\kappa$  is a lattice isomorphism (Muravitsky),  $\lambda$  is a meet epimorphism (Kuznetsov's Theorem) and  $\mu$  is also a meet epimorphism (Kuznetsov-Muravitsky).

This in particular implies that any intermediate logic is the superintuitionistic fragment of some **GL**-logic.

# KM-algebras

$\mathfrak{A} = (\mathcal{A}, \wedge, \vee, \neg, \mathbf{0}, \mathbf{1}, \Box)$ , where  $(\mathcal{A}, \wedge, \vee, \neg, \mathbf{0}, \mathbf{1})$  is a Heyting algebra (the Heyting reduct of  $\mathfrak{A}$ ) and  $\Box$  is subject to the following conditions (identities):

- $\Box x \leq x$
- $\Box x \rightarrow x = x$
- $\Box x \leq y \vee (y \rightarrow x)$

Theorem (algebraic version of Kuznetsov's Theorem)

*Any Heyting algebra can be embedded into a **KM**-algebra such that the Heyting reduct of the latter generates the same variety as the initial algebra.*

## Definition

Given algebra  $\mathfrak{A}$  and its elements  $a$  and  $a^*$ , the pair  $(a, a^*)$  is called an  $\mathcal{E}$ -pair if the following (in)equalities hold:

- $a \leq a^*$
- $a^* \rightarrow a = a$
- $a^* \leq b \vee (b \rightarrow a)$ , for any  $b \in \mathfrak{A}$ .

If  $(a, a^*)$  is an  $\mathcal{E}$ -pair, we say that  $a$  is enriched by  $a^*$  in  $\mathfrak{A}$ , or  $a^*$  enriches  $a$ .

Embedding  
 $\mathcal{E}$ -completion  
Simple  
completions

Let us fix this notation:

- an (initial) algebra  $\mathfrak{A}$ ,
- $(\mu_{\mathfrak{A}}, \subseteq)$ , the poset of the prime filters of  $\mathfrak{A}$ ,
- $\mathcal{H}(\mathfrak{A})$ , the Heyting algebra of the upward cones over  $(\mu_{\mathfrak{A}}, \subseteq)$ ,
- $h : \mathfrak{A} \rightarrow \mathcal{H}(\mathfrak{A})$ , Stone embedding,
- $\Delta X = \{F \in \mu_{\mathfrak{A}} \mid \forall F' (F \subset F' \Rightarrow F' \in X)\}$ ,
- $\mathcal{B}_{\Delta}(\mathfrak{A})$  is the subalgebra of  $\mathcal{H}(\mathfrak{A})$  generated by  $\{h(a) \mid a \in \mathfrak{A}\} \cup \{\Delta h(a) \mid a \in \mathfrak{A}\}$ .

# $\mathcal{E}$ -completion

## Definition ( $\mathcal{E}$ -completion)

We first define the following sequence of algebras:

- $\mathfrak{A}_0 = \mathfrak{A}$ ,
- $\mathfrak{A}_{i+1} = \mathcal{B}_\Delta(\mathfrak{A}_i)$ ,  $i < \omega$ .

Next we observe that  $\{\mathfrak{A}_i\}_{i < \omega}$  is a direct family of algebras and define  $\mathfrak{A} \xrightarrow{\quad}$  to be the direct limit of  $\{\mathfrak{A}_i\}_{i < \omega}$ .

## Observation

We observe the following:

- $\mathfrak{A} \xrightarrow{\quad}$  belongs to the variety generated by all  $\mathfrak{A}_i$ .
- If  $\mathfrak{A} \xrightarrow{\quad}$  is subdirectly irreducible, then all  $\mathfrak{A}_i$  and  $\mathfrak{A} \xrightarrow{\quad}$  are subdirectly irreducible as well.

# Simple completion

Notation:

- $\mathfrak{A} \preceq \mathfrak{B}$  means that  $\mathfrak{A}$  is a subalgebra of  $\mathfrak{B}$  (up to isomorphism).
- $\mathfrak{A} \lesssim \mathfrak{B}$  means that  $\mathfrak{A}$  is a relative subalgebra (up to isomorphism) of  $\mathfrak{B}$ , in which case  $\mathfrak{A}$ , considered by itself, can be regarded a partial algebra.

Definition (simple completion,  $a$ -completion)

Let  $\mathfrak{A} \preceq \mathfrak{B}$ ,  $a \in \mathfrak{A}$  and  $(a, a^*)$  be an  $\mathcal{E}$ -pair in  $\mathfrak{B}$ . Then  $\mathfrak{B}$  is called a simple completion of  $\mathfrak{A}$  if  $\mathfrak{B}$  is generated by  $\mathfrak{A} \cup \{a^*\}$ . A simple completion which depends on  $a$  is called an  $a$ -completion.

**Two Questions:**

- Why is a simple completion interesting to investigate?
- Given  $\mathfrak{A}$  and  $a \in \mathfrak{A}$ , do all  $a$ -completions form any structure?

# $\sim$ -negation

## Definition ( $\sim$ -negation)

A unary operation on a Heyting algebra is called a  $\sim$ -negation if it satisfies the following conditions (identities):

- (1)  $\sim x \wedge \sim \sim x = \sim \mathbf{1}$ ;
- (2)  $x \wedge \sim x \leq \sim \mathbf{1}$ ;
- (3)  $\sim x \vee \sim \sim x = \sim \mathbf{0}$ ;
- (4)  $x \vee \sim x \geq \sim \mathbf{0}$ ;
- (5)  $\sim x \leftrightarrow \sim \sim x = \sim \mathbf{1}$ ;
- (6)  $x \rightarrow y \leq \sim y \rightarrow \sim x$ ;
- (7)  $\sim \sim \mathbf{0} = \sim \mathbf{1}$ ;
- (8)  $\sim \sim \mathbf{1} = \sim \mathbf{0}$ .

A Heyting algebra  $\mathfrak{A}$  with  $\sim$ -negation will be denoted by  $(\mathfrak{A}, \sim)$  and called an expansion.

# $\sim$ -negation

## Observation

*In an expansion  $(\mathfrak{A}, \sim)$ ,  $[\sim\mathbf{1}, \sim\mathbf{0}]$ ,  $\vee, \wedge, \sim$  is a Boolean algebra.*

## Proposition

*If  $(a, a^*)$  is an  $\mathcal{E}$ -pair in  $\mathfrak{A}$ , then the operation*

$$\sim x = (x \rightarrow a) \wedge a^*$$

*is a  $\sim$ -negation in  $\mathfrak{A}$ . Conversely, if  $(\mathfrak{A}, \sim)$  is an expansion then  $(\sim\mathbf{1}, \sim\mathbf{0})$  is an  $\mathcal{E}$ -pair of  $\mathfrak{A}$ .*

## Corollary

*Given  $a \in \mathfrak{A}$ , let  $\mathfrak{B}$  be an  $a$ -completion of  $\mathfrak{A}$ . Then a  $\sim$ -negation can be defined in  $\mathfrak{B}$  such that  $a = \sim\mathbf{1}$ , in which case a unique  $a^*$  that enriches  $a$  equals  $\sim\mathbf{0}$ .*

# $a$ -expansion, $\Delta a$ -expansion

## Definition ( $a$ -expansion)

Given  $a \in \mathfrak{A}$ , an expansion  $(\mathfrak{A}, \sim)$  is called an  $a$ -expansion of  $\mathfrak{A}$  if  $\sim \mathbf{1} = a$ .

## Observation

Let  $a \in \mathfrak{A}$ . Then the algebra  $\mathfrak{A}_a^\Delta$  which is defined as the subalgebra of  $\mathcal{H}(\mathfrak{A})$  generated by  $\{h(x) \mid x \in \mathfrak{A}\} \cup \{\Delta h(a)\}$  is (up to isomorphism) an  $a$ -expansion of  $\mathfrak{A}$ .

## Definition ( $\Delta a$ -expansion)

Given an algebra  $\mathfrak{A}$  and  $a \in \mathfrak{A}$ , let us consider the  $h(a)$ -expansion  $(\mathfrak{A}_a^\Delta, \sim)$  of  $\mathfrak{A}_a^\Delta$  that corresponds to the  $\mathcal{E}$ -pair  $(h(a), \Delta h(a))$  of  $\mathfrak{A}_a^\Delta$ . Restricting the operation  $\sim$  to  $\mathfrak{A}$ , we define  $(\mathfrak{A}, \sim) \lesssim (\mathfrak{A}_a^\Delta, \sim)$  and call the former (possibly) **partial algebra** a  $\Delta a$ -expansion of  $\mathfrak{A}$ . One can observe that, given  $a \in \mathfrak{A}$ , a  $\Delta a$ -expansion is unique (up to isomorphism).

# packing, relation $\triangleleft$

If  $(\mathfrak{A}, \sim)$  is a  $\Delta a$ -expansion, for some  $a \in \mathfrak{A}$ , then  $a = \sim \mathbf{1}$ . This observation gives rise to the following.

## Definition (packing, relation $\triangleleft$ )

Let  $\mathfrak{A} \preceq \mathfrak{B}$ . If a  $\sim$ -negation can be defined in  $\mathfrak{B}$  so that  $\sim \mathbf{1} \in \mathfrak{A}$  and the expansion  $(\mathfrak{B}, \sim)$  is generated by  $\mathfrak{A}$ , we say that  $\mathfrak{A}$  is packed in  $\mathfrak{B}$  w.r.t. this  $\sim$ -negation.

Accordingly, we write  $(\mathfrak{A}, \sim) \triangleleft (\mathfrak{B}, \sim)$  if the following conditions are fulfilled:

- (1)  $\mathfrak{A} \preceq \mathfrak{B}$ ;
- (2)  $(\mathfrak{B}, \sim)$  is an expansion;
- (3)  $(\mathfrak{A}, \sim) \preceq (\mathfrak{B}, \sim)$ ;
- (4)  $\sim \mathbf{1} \in \mathfrak{A}$ ;
- (5)  $(\mathfrak{B}, \sim)$  is generated by  $\mathfrak{A}$ .

Kuznetsov's  
Theorem  
revisited

Embedding  
 $\mathcal{E}$ -completion  
Simple  
completions

## Remark:

Thus  $(\mathfrak{A}, \sim) \triangleleft (\mathfrak{B}, \sim)$ , for some  $\sim$ , iff  $\mathfrak{A}$  is packed in  $\mathfrak{B}$ .

## Observation

*If an algebra  $\mathfrak{A}$  is packed in an algebra  $\mathfrak{B}$  w.r.t  $\sim$ , then  $\mathfrak{B}$  is generated as a Heyting algebra by  $\mathfrak{A} \cup \{\sim \mathbf{0}\}$ .*

## Theorem

*Given a  $\Delta a$ -expansion  $(\mathfrak{A}, \sim)$ , there is an expansion  $(\mathfrak{A}^*, \sim)$  such that  $(\mathfrak{A}, \sim) \triangleleft (\mathfrak{A}^*, \sim)$ . Moreover, for any expansion  $(\mathfrak{B}, \sim)$ , if  $(\mathfrak{A}, \sim) \triangleleft (\mathfrak{B}, \sim)$  then there is a homomorphism of  $(\mathfrak{A}^*, \sim)$  onto  $(\mathfrak{B}, \sim)$ , which is an isomorphism on  $\mathfrak{A}$ .*

# poset $(\mathcal{A}, \leq)$

## Definition

Given a  $\Delta a$ -expansion  $(\mathfrak{A}, \sim)$ , we define

$$\mathcal{A} = \{(\mathfrak{A}_i, \sim) \mid (\mathfrak{A}, \sim) \triangleleft (\mathfrak{A}_i, \sim), i \in I\}.$$

Also, we define

$$(\mathfrak{A}_i, \sim) \leq (\mathfrak{A}_j, \sim)$$

if there is a homomorphism of the latter onto the former, which is an isomorphism on  $\mathfrak{A}$ .

## Theorem

$(\mathcal{A}, \leq)$  is a poset which is a join semilattice with the top element  $(\mathfrak{A}^*, \sim)$  and minimal elements.

# minimal elements of $(\mathcal{A}, \leq)$

## Definition (relation $\triangleleft$ )

We write  $(\mathfrak{A}, \sim) \triangleleft (\mathfrak{B}, \sim)$  if the following conditions are satisfied:

- $(\mathfrak{A}, \sim) \triangleleft (\mathfrak{B}, \sim)$ ;
- $\mathfrak{A}$  and  $\mathfrak{B}$  are subdirectly irreducible;
- $\mathfrak{A}$  and  $\mathfrak{B}$  share their pre-top element.

## Theorem

If an initial algebra  $\mathfrak{A}$  is s.i. then, an expansion  $(\mathfrak{A}_i, \sim)$  is minimal in  $(\mathcal{A}, \leq)$  iff  $(\mathfrak{A}, \sim) \triangleleft (\mathfrak{A}_i, \sim)$ .

## Corollary

If  $\mathfrak{A}$  is s.i. then any its expansion  $(\mathfrak{A}_a^\Delta, \sim)$  is minimal in  $(\mathcal{A}, \leq)$ .
