Plan of my talk

- ▶ A sketch of type theory
- ▶ Models
- ▶ The notion of tribe
- ▶ The category of tribes

A sketch of type theory

- ▶ Types, elements, judgments and contexts
- ▶ Judgmental equality
- ▶ Substitution rules
- ▶ Σ -formation and introduction rules
- ▶ Π -formation and introduction rules
- ▶ Propositional equality
- ▶ Universes
- ▶ Univalence

Types and judgments

The basic notion is that of a **type** (\simeq set).

The assertion that A is a type is formally expressed by writing

$$\vdash A : \textit{Type}$$

This expression is an instance of what is called a **judgment**.

For example, the judgment

$$\vdash \mathbb{N} : \textit{Type}$$

asserts that the set \mathbb{N} of natural numbers is a type.

Elements, terms

The assertion that x is an **element** of type A is formally expressed by the judgment

$$\vdash x : A$$

For example, the judgment

$$\vdash 0 : \mathbb{N}$$

asserts that 0 is a natural number.

An element $x : A$ is often called a **term**.

There are terms forming operations

$$t ::= x \mid \lambda x. t \mid t(t') \mid c \mid f$$

Judgmental equality

In Martin-Löf type theory, two objects are **intentionally equal** if they have the **same normal form**.

The assertion that two elements x and y of type A are intentionally equal is written as a judgment:

$$\vdash x \equiv y : A$$

Also the assertion that two types A and B are intentionally equal,

$$\vdash A \equiv B$$

Dependant types and contexts

A type $B(x)$ may depend on a parameter x ranging in a type A .

$$x : A \vdash B(x) : \textit{Type}$$

The expression $x : A$ on the left of the symbol \vdash is the **context** of the judgment.

An element of type $B(x)$ may depend on x :

$$x : A \vdash t(x) : B(x)$$

Contexts may be concatenated:

$$y : B(x), x : A \vdash C(x, y) : \textit{Type}$$

Substitution rules

There are *substitution rules* for types and terms:

$$\frac{x : A \vdash f(x) : B, \quad y : B \vdash E(y) : \text{Type}}{x : A \vdash E(f(x)) : \text{Type}}$$

$$\frac{x : A \vdash f(x) : B, \quad y : B \vdash s(y) : E(y)}{x : A \vdash s(f(x)) : E(f(x))}$$

Σ -formation rules

There is a *formation rule* for the sum (= disjoint union) of a dependant type $E(x)$ in context $x : A$.

$$\frac{x : A \vdash E(x) : \text{Type}}{\vdash \sum_{x:A} E(x) : \text{Type}}$$

There is an *introduction rule* for pairs:

$$\frac{\vdash a : A, \quad \vdash b : E(a)}{\vdash (a, b) : \sum_{x:A} E(x)}$$

Π -formation rules

There is a *formation rule* for the product of a dependant type $E(x)$ in context $x : A$.

$$\frac{x : A \vdash E(x) : \text{Type}}{\vdash \prod_{x:A} E(x) : \text{Type}}$$

There is an *introduction rule* for λ -term and an *elimination rule*:

$$\frac{x : A \vdash t : E(x)}{\vdash \lambda x. t : \prod_{x:A} E(x)} \qquad \frac{\vdash f : \prod_{x:A} E(x), \quad \vdash a : A}{\vdash f(a) : E(a)}$$

As usual, the term $\lambda x. t(x)$ stands for the map $x \mapsto t(x)$.

Computation and uniqueness rules

There is a computation rule:

$$\frac{\vdash \lambda x.t(x) : \prod_{x:A} E(x), \quad \vdash a : A}{\vdash (\lambda x.t(x))(a) \equiv t(a)}$$

and a uniqueness rule:

$$\frac{\vdash f : \prod_{x:A} E(x)}{\vdash f \equiv \lambda x.f(x)}$$

Equality type

There is a type constructor which associates to a type A another type Eq_A , called the **equality type** of A ,

$$\frac{\vdash A : Type}{x, y : A \vdash Eq_A(x, y) : Type}$$

A term $p : Eq_A(x, y)$ is a *proof* that $x \simeq y$ (propositional equality).

The axiom that $x \simeq x$ is given by a term $r(x)$ called the **reflexivity term**:

$$\frac{A : Type}{x : A \vdash r(x) : Eq_A(x, x)}$$

The J -operation

There is a term constructor J which associates to a dependant type

$$z : Eq_A(x, y), x, y : A \vdash E(z) : Type$$

together with a term $x : A \vdash t : E(r(x))$, another term

$$z : Eq_A(x, y), x, y : A \vdash J(t)(z) : E(z).$$

There is also a *computation rule*:

$$x : A \vdash J(t)(r(x)) \equiv t : E(r(x))$$

Universes

We postulate an infinite sequences of universes

$$\vdash \mathcal{U}_0 : \mathcal{U}_1 : \mathcal{U}_2 : \dots$$

with the axioms:

(1) Every type A is a term in some universe \mathcal{U}_i .

$$\vdash A : \mathcal{U}_i$$

(2) Every term in \mathcal{U}_i is a term in \mathcal{U}_{i+1} .

$$\frac{A : \mathcal{U}_i}{A : \mathcal{U}_{i+1}}$$

The groupoid model

Hofmann and Streicher:

Type theory has a model in groupoids.

- ▶ types \rightsquigarrow groupoids;
- ▶ terms \rightsquigarrow objects of a groupoid;
- ▶ dependant types in context $A \rightsquigarrow$ fibrations $E \twoheadrightarrow A$;
- ▶ proofs that $a \simeq b \rightsquigarrow$ isomorphisms $a \rightarrow b$.

The simplicial set model

Awodey, Warren, Veovodsky :

Type theory has a model in simplicial sets

- ▶ types \rightsquigarrow Kan complexes;
- ▶ terms \rightsquigarrow vertices of a Kan complex;
- ▶ dependant types in context A \rightsquigarrow Kan fibrations $E \twoheadrightarrow A$;
- ▶ proofs that $a \simeq b$ \rightsquigarrow paths $a \rightarrow b$.

Fibrations and dependant types

The **fiber** $E(x)$ of a fibration $p : E \rightarrow A$ at a point $x \in A$ is defined by the pullback square

$$\begin{array}{ccc} E(x) & \longrightarrow & E \\ \downarrow & & \downarrow p \\ \star & \xrightarrow{x} & A. \end{array}$$

A fibration $p : E \rightarrow A$ can be regarded as a **family** $(E(x) : x \in A)$ of objects parametrized by a variable element $x \in A$.

A fibration $p : E \rightarrow A$ is a **dependant type** in context A .

Equivalences

For any two types A and B , there is a type $\mathit{Equiv}(A, B)$ whose elements are the equivalences $A \cong B$.

An **equivalence** $w : A \cong B$ is a quintuple $w \equiv (f, g_1, g_2, h_1, h_2)$, where

$$f : A \rightarrow B \quad \text{and} \quad g_1, g_2 : B \rightarrow A$$

are maps and

$$h_1 : g_1 \circ f \simeq \mathit{id}_A \quad \text{and} \quad h_2 : f \circ g_2 \simeq \mathit{id}_B$$

are terms.

Univalence

For any type $B(x)$ which depends on $x : A$ there is a canonical map

$$\alpha : Eq_A(x, y) \rightarrow Equiv(B(x), B(y))$$

which depends on $x, y : A$.

Univalence axiom (Voevodsky): If \mathcal{U} is an universe, then the map

$$\alpha : Eq_{\mathcal{U}}(A, B) \rightarrow Equiv(A, B)$$

is an equivalence for every $A, B : \mathcal{U}$.

Results and problems

Results:

- ▶ Shulman: $\pi_1(S^1) = \mathbb{Z}$
- ▶ Licata: $\pi_n(S^n) = \mathbb{Z}$ for $n > 0$, $\pi_k(S^n) = 0$ for $k < n$,
- ▶ Brunerie: $\pi_3(S^2) = \mathbb{Z}$
- ▶ Lumsdane, Finster, Licata: Freudenthal suspension theorem.

Problems:

- ▶ $\pi_4(S^3) = \mathbb{Z}/2$?
- ▶ No good notion of (internal) simplicial object
- ▶ No notion of $(\infty, 1)$ -categories.

Axiomatic Homotopy Theory

J.H.C. Whitehead (1950):

The ultimate aim of algebraic homotopy is to construct a purely algebraic theory, which is equivalent to homotopy theory in the same sort of way that analytic is equivalent to pure projective geometry.

Examples of axiomatic systems in homotopy theory:

- ▶ Triangulated categories (Verdier 1963);
- ▶ Homotopical algebra (Quillen 1967);
- ▶ Fibration categories (Brown 1973);
- ▶ Homotopy theories (Heller 1988)
- ▶ Theory of derivators (Grothendieck 198?)
- ▶ Homotopy type theory

Fibration structure

Let \mathcal{C} be a category with terminal object \star .

Definition

A **fibration structure** on \mathcal{C} is a class of maps $\mathcal{F} \subseteq \mathcal{C}$ called **fibrations** and denoted $A \twoheadrightarrow B$, satisfying the following conditions:

- ▶ Every isomorphism is a fibration;
- ▶ The composite of two fibrations is a fibration;
- ▶ the base change of fibration along any map exists and is a fibration;

$$\begin{array}{ccc} A \times_B E & \longrightarrow & E \\ g \downarrow & & \downarrow f \\ A & \xrightarrow{u} & B \end{array}$$

- ▶ the map $X \rightarrow \star$ is a fibration for every object $X \in \mathcal{C}$.

Anodyne maps

Let \mathcal{C} be a category equipped with a fibration structure.

Definition

A map $u : A \rightarrow B$ in \mathcal{C} is said to be **anodyne** if it has the left lifting property with respect to every fibration $f : X \rightarrow Y$.

This means that every commutative square

$$\begin{array}{ccc} A & \xrightarrow{a} & X \\ u \downarrow & & \downarrow f \\ B & \xrightarrow{b} & Y \end{array}$$

has a diagonal filler $d : B \rightarrow X$ ($du = a$ and $fd = b$).

Tribes

Definition

A **tribe** \mathcal{C} is a category equipped with a fibration structure such that:

- ▶ every map $f : A \rightarrow B$ admits a factorization $f = pu$ with u anodyne and p a fibration.

- ▶ the base change of an anodyne map along a fibration is anodyne.

The local tribe $\mathcal{C}(A)$

Let A be an object of a tribe \mathcal{C} .

The **local tribe** $\mathcal{C}(A)$ is defined to be the full sub-category of \mathcal{C}/A whose objects are the fibrations $p : E \twoheadrightarrow A$ with codomain A .

A map $f : (E, p) \rightarrow (F, q)$ in $\mathcal{C}(A)$ is a fibration if the map $f : E \rightarrow F$ is a fibration in \mathcal{C} .

An object of $\mathcal{C}(A)$ is a **dependent type** in **context** A .

Homomorphism of tribes

If \mathcal{C} and \mathcal{D} are tribes.

A functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is a **homomorphism** if

- ▶ it takes fibrations to fibrations;
- ▶ it takes anodyne maps to anodyne maps;
- ▶ it preserves base changes of fibrations;
- ▶ it preserves terminal objects.

For example, if $u : A \rightarrow B$ is a map in a tribe \mathcal{C} , then the base change functor $u^* : \mathcal{C}(B) \rightarrow \mathcal{C}(A)$ is a homomorphism of tribes.

Remark: The category of tribes is a 2-category, where a 1-cell is a homomorphism and 2-cell is a natural transformation.

Product along a fibration

A fibration $f : A \rightarrow B$ induces a base change functor

$$f^* : \mathcal{C}/B \rightarrow \mathcal{C}/A$$

The **product along** $f : A \rightarrow B$ of an object $E = (E, p) \in \mathcal{C}/A$ is an object $\Pi_f(E) \in \mathcal{C}/B$ equipped with a map

$$\epsilon : f^*(\Pi_f(E)) \rightarrow E$$

which is couniversal with respect to the functor f^* .

For every $y : B$ we have

$$\Pi_f(E)(y) = \prod_{f(x)=y} E(x)$$

Definition

We say that a tribe \mathcal{C} is a π -**tribe**, if for every fibration $f : A \rightarrow B$

- ▶ the product $\Pi_f(E)$ exists for every $E \in \mathcal{C}(A)$ and the structure map $\Pi_f(E) \rightarrow B$ is a fibration.
- ▶ the functor $\Pi_f : \mathcal{C}(A) \rightarrow \mathcal{C}(B)$ preserves anodyne maps.

If \mathcal{C} is a π -tribe, then so is the tribe $\mathcal{C}(A)$ for every object $A \in \mathcal{C}$.

Path objects in a Quillen model category

If \mathcal{M} is a Quillen model category.

A **path object** for $A \in \mathcal{M}$ is obtained by factoring the diagonal $\Delta : A \rightarrow A \times A$ as an anodyne map $r : A \rightarrow PA$ followed by a fibration $(s, t) : PA \rightarrow A \times A$,

$$\begin{array}{ccc} & PA & \\ r \nearrow & & \searrow (s,t) \\ A & \xrightarrow{\Delta} & A \times A. \end{array}$$

The identity type is a path object

Awodey-Warren:

The identity type $Eq_A \rightarrow A \times A$ is a path object for A .

The J -rule implies that the reflexivity term $r : A \rightarrow Eq_A$ is anodyne.

Thus, if $p : E \twoheadrightarrow Eq_A$ is a fibration, then every commutative square

$$\begin{array}{ccc} A & \xrightarrow{t} & E \\ r \downarrow & & \downarrow p \\ Eq_A & \xlongequal{\quad} & Eq_A \end{array}$$

has a diagonal filler $d = J(t)$,

Homotopic maps

Let \mathcal{C} be a tribe.

A **homotopy** $h : f \rightsquigarrow g$ between two maps $f, g : A \rightarrow B$ in \mathcal{C} is a map $h : A \rightarrow PB$ such that $sh = f$ and $th = g$.

Theorem

The homotopy relation $f \sim g$ is a congruence on the arrows of \mathcal{C} .

The homotopy category

Let \mathcal{C} be a tribe.

The **homotopy category** $Ho(\mathcal{C})$ is the quotient category \mathcal{C}/\sim .

A map $f : X \rightarrow Y$ in \mathcal{C} is called a **homotopy equivalence** if it is invertible in $Ho(\mathcal{C})$.

Every anodyne map is a homotopy equivalence.

An object X is **contractible** if the map $X \rightarrow \star$ is a homotopy equivalence.

Brown fibration category

Definition

(Ken Brown) A **Brown fibration category** is a category \mathcal{E} equipped with a fibration structure together with a class of **acyclic maps** such that:

- ▶ Every isomorphism is acyclic;
- ▶ The class of acyclic maps has the 3-for-2 property;
- ▶ Every morphism can be factored as an acyclic map followed by a fibration;
- ▶ The class of acyclic fibrations is stable under base change.

Theorem

A tribe is a Brown fibration category if the acyclic maps are the homotopy equivalences.

Forthcoming Phd thesis of Page North in Cambridge.

Weak equivalences of tribes

Definition

We say that a homomorphism of tribes $F : \mathcal{E} \rightarrow \mathcal{E}'$ is a **weak-equivalence** if the induced functor $Ho(F) : Ho(\mathcal{E}) \rightarrow Ho(\mathcal{E}')$ is an equivalence of categories.

Theorem

A map $f : A \rightarrow B$ in a tribe \mathcal{E} is a homotopy equivalence if and only if the functor $f^ : \mathcal{E}(B) \rightarrow \mathcal{E}(A)$ is a weak-equivalence of tribes.*

Meta-fibrations

Definition

We say that a homomorphism of tribes $F : \mathcal{E} \rightarrow \mathcal{E}'$ is a **meta-fibration** if the following conditions are satisfied:

- ▶ F and $Ho(F)$ are iso-fibrations;
- ▶ F is full on sections of trivial fibrations;
- ▶ F is full on diagonal filler of AF -squares;
- ▶ F is full on AF -factorisations.

For example, if \mathcal{E} is a tribe, then the functor $\partial_1 : \mathcal{E}^{(1)} \rightarrow \mathcal{E}$ is a meta-fibration.

The base change of a meta-fibration along a homomorphism of tribes is a meta-fibration.

A fibration category of tribes?

- ▶ Objects \rightsquigarrow tribes
- ▶ morphisms \rightsquigarrow homomorphisms of tribes
- ▶ fibrations \rightsquigarrow meta-fibrations
- ▶ Acyclic morphism \rightsquigarrow weak equivalences of tribes

Theorem

The base change of an acyclic meta-fibration along a homomorphism of tribes is an acyclic meta-fibration.

I was not able to prove that every homomorphism can be factored as an acyclic homomorphism followed by a meta-fibration. Stronger axioms are needed.

Simplicial tribes

A **simplicial tribe** is a category enriched over simplicial sets having the structure of a tribes + compatibility axioms.

Theorem

The category of simplicial tribes has the structure of a Brown fibration category.

There is a relation with the work of Karol Szumilo.

THANK YOU FOR YOUR ATTENTION!
